19 **Abstract**

20 There has been an increasing interest in enhancing freshwater aquaculture processes without  
21 hindering the progress of the Water Framework Directive. Bord Iascaigh Mhara (Ireland's national  
22 seafood development organisation), undertook a feasibility study to assess the potential use of  
23 peatlands (bogs) for sustainable aquaculture diversification. AquaMona, a new concept in integrated  
24 multitrophic aquaculture (IMTA), uses cutaway bogs to farm rainbow trout and Eurasian perch with  
25 associated organic status that is powered by wind energy and utilizes algae and duckweed to treat  
26 rearing water. Approximately 5% of Ireland comprises bogs that support natural ecosystems where  
27 there is a pressing need to develop alternative innovation to that of burning peat in order to reduce  
28 Ireland's carbon emissions. This constitutes the first study to evaluate water quality from this new  
29 IMTA where intake and terminal holding tank samples were evaluated from May to August 2019.  
30 Physicochemical parameters (temperature, pH, nitrogen, phosphorus, oxygen, suspended solids,

31 hardness and alkalinity), and ecotoxicological bioassays (*Pseudokirchneriella subcapitata* and  
32 *Daphnia pulex*), were used to investigate the potential effects that introducing aquaculture processes  
33 may have on peatlands. Nitrite ( $p < 0.001$ ), Nitrate ( $p = 0.016$ ), and chemical oxygen demand ( $p = 0.011$ ),  
34 were the only physicochemical parameters that differed significantly between the intake and holding  
35 tank water indicating that water quality for the most part remained unchanged. Low levels of toxicity  
36 were observed between the bioassays suggested the introduction of the processes into the bog were  
37 unlikely to cause adverse effects on the ecosystem and the organisms therein. Observations  
38 determined in this study were similar to or lower than those determined for intensive flow-through  
39 aquaculture processes that discharge to receiving water. Findings from this study support the use of  
40 peatlands as future locations for integrated aquaculture processes.

43 multitrophic system

44

## 45 1. Introduction

46 Aquaculture is the fastest growing food producing industry globally (Fečkaninová *et al.*, 2017; Liu  
47 *et al.*, 2017; O'Neill *et al.*, 2019). It affords one of the most sustainable forms of edible protein (Liu *et al.*,  
48 2017; Yue and Wang, 2017). Aquacultures rapid expansion has resulted in response to dramatic  
49 increase in global population and an augmented demand for food (Seoane *et al.*, 2014). Between  
50 1983 and 2003, global capture fisheries production increased from 71.1 M (million), to 92.6 M tonnes  
51 globally, whilst global aquaculture production increased from 6.2 M to 70.2 M tonnes (Ottinger *et al.*,  
52 2016). In 2014, aquaculture production reached 73.8 M tonnes (Huynh *et al.*, 2017), and now  
53 accounts for ~50% of fishery products produced for human consumption (Liu *et al.*, 2017). Fredricks  
54 *et al.* (2015), suggests that by 2030 aquaculture will provide an estimated 62% of fish for human  
55 consumption. However, limitations in space that would allow for expansion of existing facilities,  
56 challenges with the development of new sites due to licencing, the lack of availability of freshwater,  
57 and the ever growing concerns associated with pollution are thought to be major hurdles in the further  
58 expansion of traditional aquaculture systems (Badiola *et al.*, 2012). Concerns about the environmental  
59 impacts of the rapid expansion of intensive aquaculture systems has also led to increased research  
60 interest in integrated multitrophic aquaculture systems or IMTA (Granada *et al.*, 2016)

61 The Irish aquaculture industry was valued at €208.4 M in 2017, producing just over 47,000  
62 tonnes of fish (Bord Iascaigh Mhara, 2018). The industry provides valuable employment and assists in  
63 preserving rural communities (Department of Agriculture Food and the Marine, 2015a). Food Wise  
64 2025 is a national strategy put forward by the government of Ireland to assist in the growth and  
65 development of the Irish agri-food industry, which includes seafood (Department of Agriculture Food  
66 and the Marine, 2015b). Food Wise 2025 has projected that the Agri-Food industry, or more  
67 specifically exports, have the potential to grow to €19 billion per annum by 2025 (Department of  
68 Agriculture Food and the Marine, 2015b). This growth will, in part, be achieved by expansion in the  
69 seafood sectors (Department of Agriculture Food and the Marine, 2015b). As part of the Food Wise  
70 2025 strategy and in order to assist in meeting this goal, it has been predicted that the Irish  
71 aquaculture industry has the potential to increase export production to 81,700 tonnes by 2023  
72 (Department of Agriculture Food and the Marine, 2015b). However, issues associated with 1) the Irish  
73 aquaculture licensing process, and 2) the potential environmental impacts caused by aquaculture and  
74 its discharge which will have an effect on the environmental EU directives adopted by Ireland  
75 (Department of Agriculture Food and the Marine, 2015b), have hampered the industry reaching this  
76 goal.

77 There has been increasing interest in enhancing sustainable freshwater aquaculture processes  
78 through innovation (Tahar *et al.*, 2018a, 2018b; Rowan, 2019). However, enhancement must not be at  
79 the expense of the commitments set out by the Water Framework Directive (WFD), which aims to  
80 provide a structure for water protection to assist EU member states to achieve good water status in all  
81 waters and ensure this status does not depreciate (Voulvoulis *et al.*, 2017; WFD Ireland, 2018). As  
82 part of the 2015 National Strategic Plan for Sustainable Aquaculture Development, Bord Iascaigh  
83 Mhara (BIM), the state agency for developing Ireland's seafood industry, undertook a feasibility study  
84 to assess the novel use of Irish bogs for aquaculture diversification (Department of Agriculture Food  
85 and the Marine, 2015a). Peatlands (bogs) are wetland environments characterised by the build-up of  
86 organic matter (peat), derived from dead plant material that is slowly decomposing under wet  
87 conditions. Bord na Móna, a state company that was originally developed to establish Irish peat  
88 resources for economic benefit owns or controls approximately 7% or about 80,000 hectares of  
89 Ireland's bogs. Cutaway-bog sites that were taken out of production when there is no economic  
90 supply of peat remaining have been converted to wind energy, forestry, biodiversity, amenity, and

91 waste management. Recently, Bord Na Mona, in conjunction with BIM, has further expanded use of  
92 these cutaway bogs to develop Ireland's first integrated recirculation aquaculture process for fish  
93 production using organic principles that comprises a combined split pond and duckweed culture  
94 lagoons (Bord na Móna, 2019). The trial fish farm was established at a peatland site of a wind farm at  
95 Mount Lucas, Co Offaly which is situated in the centre of Ireland. The trial farm, is based on  
96 sustainable multitrophic culture system principles, holding European perch (*Perca fluviatilis*), rainbow  
97 trout (*Oncorhynchus mykiss*), common duckweed (*Lemna minor*) and gibbous duckweed (*Lemna*  
98 *gibba*).

99 Bogs primarily make up Ireland's peatlands (National Parks & Wildlife Service, 2015). Irish bogs  
100 can be divided into two main categories; blanket bogs and raised bogs where the latter is the focus of  
101 this study. Raised bogs are best described as raised bodies of peat situated in former lakes or  
102 shallow hollows in the landscape (Irish Peatland Conservation Council, 2019). They were formed  
103 thousands of years ago, after the last ice age when much of Ireland was covered in depthless lakes  
104 as a result of the melting ice (Ward *et al.*, 2019). Over the centuries, poor drainage and the build-up of  
105 decaying plants have resulted in the raised bogs we know today. They are only fed by precipitation  
106 (rainfall), and as a consequence are generally poor in nutrients (National Parks & Wildlife Service,  
107 2015; Ward *et al.*, 2019). Irish raised bogs are normally found in the midlands where moderate levels  
108 of rainfall are experienced, and are very deep, *i.e.* up to 13 m in parts (National Parks & Wildlife  
109 Service, 2015; Ward *et al.*, 2019). Thus, fish farms from cutaway bogs differ from traditional  
110 aquaculture practices that use water from rivers and lakes where latter system must consider  
111 environmental impact of their expansion and possible threats arising from potential pollutants from  
112 agricultural runoff, industry and waste-water treatments plants (Tahar *et al.*, 2017; Tahar *et al.*, 2018c;  
113 Tiedeken *et al.*, 2018).

114 Irish bogs are considered to be some of the finest examples of their type in the world (Flynn *et*  
115 *al.*, 2016; Irish Peatland Conservation Council, 2019). Raised bogs are important reservoirs of  
116 biodiversity (Flynn *et al.*, 2016), and are home to a range plant and animal species, such as bog  
117 cotton, frogs and moths, which are highly adapted to the bogs inhospitable conditions of low-nutrient  
118 soil and waterlogging (Ward *et al.*, 2019). As a result, Ireland has a responsibility to conserve and  
119 protect them.

120 Bogs are important carbon stores which help to control greenhouse gases (Flynn *et al.*, 2016;  
121 Irish Peatland Conservation Council, 2019). However, human activities and inputs have caused  
122 degradation. The remaining intact bogs are small remnants of once larger bog systems. It is thought  
123 that there has been as much as a 99% loss in bog habitats (Flynn *et al.*, 2016). For example,  
124 Hammond (1981), reported that 16.2% of the island of Irelands landscape was covered in peatlands.  
125 Today, on the other hand, it is down to only 5% (Ward *et al.*, 2019).

126 Bord na Móna was formed in 1946 by the Irish Government from the Turf Development Board  
127 after the introduction of the Turf Development Act (Bord na Móna, 2019; Ganly, 2017). The now semi-  
128 state owned company was originally established to aid in the development of a large scale peat  
129 industry for the state's economic gain (Bord na Móna, 2019; Ganly, 2017; Ward *et al.*, 2019). Peat  
130 has been used for centuries in Ireland as a fuel source for both domestic (heating homes), and later  
131 commercial use (generate electricity via power plants), as it is a country with very little oil, gas or coal  
132 (Toner, 2018). However, peat is considered to be very damaging to the environment, emitting more  
133 carbon dioxide than coal and natural gas (Toner, 2018). In 2016, peat generated approximately 8% of  
134 Ireland's total electricity which was the equivalent to 20% of the sectors annual carbon emissions  
135 (Toner, 2018).

136 The urgent threat of climate change, an ever complicated and increasingly problematic  
137 challenge, in addition to some of the bogs now being listed as important habitats under the European  
138 Unions (EU), Birds and Habitats Directives due to their scarcity, have resulted in dramatic changes in  
139 the peat industry (Bord na Móna, 2019; Irish Peatland Conservation Council, 2019; O'Neill *et al.*,  
140 2019; Toner, 2018; Ward *et al.*, 2019). Bord na Móna are now moving away from peat harvesting  
141 (Bord na Móna, 2019; Lee, 2018). In 2018, 17 of their 62 active harvesting sites were closed and all  
142 works will cease on the remaining 42 sites by 2025 (Lee, 2018). Because of the need to decarbonise  
143 energy sources to in response to climate change, Bord na Móna has diversified its portfolio of works  
144 to include renewable energy (Bord na Móna, 2019; Lee, 2018), with more than 60% of electricity  
145 generated now coming from renewable resources *e.g.* wind turbines (Bord na Móna, 2019).

146 Aquaculture discharge typically contains nutrient rich waste which requires treatment prior to  
147 release (Jegatheesan *et al.*, 2011; Martinez-Porchas *et al.*, 2014; Ngo *et al.*, 2016; O'Neill *et al.*, 2019;  
148 Sikder *et al.*, 2016). If discharged untreated, this waste can lead to water pollution in the environment  
149 (Jegatheesan *et al.*, 2011; O'Neill *et al.*, 2019; Sikder *et al.*, 2016). Water quality is generally

150 assessed by measuring physicochemical parameters (da Silva *et al.*, 2017), such as temperature, pH,  
151 phosphorus, nitrogen, oxygen, suspended solids, hardness and alkalinity. Temperature and dissolved  
152 oxygen affects the growth and survival of fish and are therefore a critical environmental factors  
153 (Ferreira *et al.*, 2011). Ammonium ( $\text{NH}_4^+$ ) and nitrite ( $\text{NO}_2^-$ ) are toxic to aquatic life and require  
154 treatment by way of conversion to nitrate ( $\text{NO}_3^-$ ) before being released from fish farms (Celik *et al.*,  
155 2001; Durborow *et al.*, 1997; Pollice *et al.*, 2002; Zhang *et al.*, 2011). Orthophosphate ( $\text{PO}_4^{3-}$ ), is a  
156 reactive form of phosphorus and is one of the main causes of algal blooms and hypoxic conditions  
157 that blooms ensue (Barcellos *et al.*, 2019; Brogan *et al.*, 2001; O'Neill *et al.*, 2019). The biochemical  
158 oxygen demand (BOD), is the amount of oxygen bacteria use to break down organic matter, whilst the  
159 chemical oxygen demand (COD), measures the level of stress the organic matter puts on the  
160 receiving water system (Lee and Nikraz, 2015). Suspended solids usually consist of organic matter  
161 and eutrophic conditions can occur when levels become elevated (Bilotta and Brazier, 2008; O'Neill *et al.*  
162 *et al.*, 2019). Analysis of these parameters alone, although important, will only indicate potential  
163 adverse effects at a given time and not the effects on the ecosystem or organisms therein (da Silva *et al.*  
164 *et al.*, 2017; O'Neill *et al.*, 2019; Stephens and Farris, 2004a). Therefore, ecotoxicological bioassays are  
165 used in conjunction with the physicochemical parameters (da Silva *et al.*, 2017). This may be very  
166 important as ultimately the WFD is not concerned with exact emission levels as such, but rather what  
167 can be emitted such that harmful effects can be avoided and good or excellent status can be both  
168 achieved and maintained (WFD Ireland, 2001).

169 Primary producers (*e.g.* algae), and primary consumers (*e.g.* micro-crustaceans), are key  
170 components in aquatic food chains (Aruoja, 2011). The microalgae *Pseudokirchneriella subcapitata*  
171 (*P. subcapitata*), is commonly used for ecotoxicological assessment of primary producers in multi-  
172 trophic testing due to its high sensitivity, reproducibility and growth rate (Suzuki *et al.*, 2018). As a  
173 result, *P. subcapitata* is one of the recommended algae set out by the ISO (6892:2012), guidelines  
174 (International Organisation for Standardisation, 2012a). *Daphnia* are freshwater micro-crustaceans  
175 are commonly used for ecotoxicological assessment of primary consumers in multi-trophic testing.  
176 Similarly with *P. subcapitata*, they also are chosen due to their reproducibility and ease of culture  
177 (International Organisation for Standardisation, 2012b).

178 The aim of this research was to determine whether the introduction of aquaculture production  
179 into peatlands had any potential adverse effects on the very important and scarce natural habitat of

180 the peatland. This in turn may assist the Irish aquaculture industry in reaching the goal of increasing  
181 production to the predicted levels set out by Food Wise 2025 as well as assist in limiting job losses  
182 that could face Bord na Móna employees once peat harvesting ceases.

183

## 184 **2. Methods**

### 185 2.1. Fish Farm

186 The multitrophic aquaculture system consists of four split (pill) ponds connected with  
187 duckweed area serves as a treatment system (Figure 1A). Fish are kept at a density that does not  
188 exceed the organic farming standard ( $< 20 \text{ kg.m}^{-3}$  for perch), using screens at the D-ends of each split  
189 pond (Figure 1B). The space between two D-end fish culture areas is also used to treat waste with  
190 free living algae and bacteria in suspension. Flow in each split pond is generated and water is  
191 circulated using an airlift. Each D-end fish culture area is equipped with oxygen and temperature  
192 probes connected to paddlewheels to provide extra oxygen when necessary. The farm is designed to  
193 hold a maximum of 32,000 Kg of fish. Holdings reached just over 11,000 Kg in August (Table 1).

194

### 195 2.2. Sampling:

196 Water samples were collected from the trial fish farm located in Mount Lucas, Co Offaly in the  
197 Republic of Ireland. The farm, which cultures perch (*Perca fluviatilis*), and rainbow trout  
198 (*Oncorhynchus mykiss*), utilises a multi trophic approach, which reuses up to 100% of its water and a  
199 large algae and duckweed bed used to assist in treating waste water (Figure 1). The bog is  
200 undergoing restoration and is in the process of returning to its natural state before peat extraction  
201 begun. The farm is adjacent to a large natural wetland.

202 Grab samples were collected in 5\_L octagonal carboy HDPE bottles (Lennox), and transported  
203 directly for laboratory analysis. Samples were obtained directly from the intake and holding tank  
204 sources of the farm every month from May to August 2019. The intake samples consisted of water  
205 taken directly from the bog. The terminal holding take samples contained water that had been used to  
206 culture fish in the split ponds and had then passed through the algae and duckweed channels for  
207 treatment. This water continues on after the holding tanks and returns to the culture ponds to be  
208 reused, thus is recirculated. As discharge only occurs during times of high rainfall, resulting in  
209 overflow, the samples were taken directly from the holding tank at the discharge point. Discharge did

210 not occur during the sampling period. Collection occurred on the same day (Wednesday), and at  
211 approximately the same time (9:00 a.m.). Sampling points are shown in Figure 1. All samples were  
212 tested in triplicate. Due to issues in collected individual and composite samples, triplicate samples  
213 were taken from the 5L grab sample and analysed separately.

214

### 215 2.3. Physicochemical analysis:

216 Water parameters, including; temperature, pH,  $\text{NH}_4^+$ ,  $\text{NO}_2^-$ ,  $\text{NO}_3^-$ ,  $\text{PO}_4^{3-}$ , DO, BOD, COD,  
217 suspended solids, hardness and alkalinity, were analysed in the laboratory within 24 hours of  
218 collection to eliminate the need for preservation. Spectroquant<sup>®</sup> photometric kits (Sigma-Aldrich), were  
219 used to assess the  $\text{NH}_4^+$ ,  $\text{NO}_2^-$ ,  $\text{NO}_3^-$ ,  $\text{PO}_4^{3-}$  and COD. Analysis was performed as per the  
220 manufacturer's instructions. Temperature and pH were analysed using a VWR pHenomenalTM MU  
221 6100L meter and VWR 111 662-1157 pH probe. DO and  $\text{BOD}_{5\text{day}}$  were analysed using a Jenway 9500  
222 Dissolved  $\text{O}_2$  meter and probe. Suspended solids were analysed via filtration using 7 cm 0.45  $\mu\text{m}$  filter  
223 paper. Hardness was assessed via titration using pH 10 buffer, Erichrome black and EDTA. Alkalinity  
224 was analysed by titration using phenolphthalein indicator, methyl orange indicator and hydrochloric  
225 acid. See Table 2 for a summary of all standard methods and their corresponding method numbers  
226 used in this research.

227

### 228 2.4. Ecotoxicity testing:

229 The freshwater unicellular green algae *P. subcapitata* (also known as *Raphidocelis*  
230 *subcapitata*), and the freshwater crustacean *Daphnia pulex* (*D. pulex*), were used in the ecotoxicity  
231 test.

232 A starter culture of the *P. subcapitata* was obtained from The Culture Collection of Algae and  
233 Protozoa (CCAP 278/4; SAMS Limited, Scottish Marine Institute, Oban, Argyll, Scotland, U.K.), and  
234 grown in standard Jarworski's medium under controlled conditions of  $23^\circ\text{C} \pm 2^\circ\text{C}$  exposed to  
235 continuous illumination (lux 6,000 – 10,000). Sub-culturing was conducted every two to three days to  
236 ensure the growth rate remained in the exponential phase. Ecotoxicity testing was conducted as per  
237 the Water quality – Fresh water algal growth inhibition test with unicellular green algae ISO  
238 (8692:2012), guidelines. The *P. subcapitata* was exposed to the intake and holding tank samples for  
239 72 hours under static conditions at  $23^\circ\text{C} \pm 2^\circ\text{C}$  exposed to the continuous illumination. Inhibition of the

240 algae growth rate, in percent, was calculated by comparing the samples to a negative control  
241 containing just the Jarworski's medium. Calculations were conducted as follows;

242

243 **Equation 1:**

$$244 \quad \text{Algal cells mL}^{-1} = \frac{n}{0.02} \times 10^3$$

245 Where n = number of cells counted using a haemocytometer

246

247 **Equation 2:**

$$248 \quad \text{Average specific growth rate } (\mu), = \frac{\ln X_n - \ln X_0}{T_n - T_0}$$

249 Where ln = natural log of

250  $X_n$  = Algae cells mL<sup>-1</sup> at 72 hours

251  $X_0$  = Algae cells mL<sup>-1</sup> at 0 hours

252  $T_n$  = Duration of test

253  $T_0$  = Time zero

254

255 **Equation 3:**

$$256 \quad \text{Percent inhibition in growth rate} = \frac{C_{\mu} - T_{\mu}}{C_{\mu}} \times 100$$

257 Where  $C_{\mu}$  = Average specific growth rate for control

258  $T_{\mu}$  = Average specific growth rate for treatment

259

260 An in-house stock of the freshwater crustacean *D. pulex*, was maintained in aerated spring  
261 water. Sub-culturing was conducted twice a week to ensure the culture conditions of the crustacean  
262 remained at optimum levels. Ecotoxicity testing was conducted as per the Water quality –  
263 Determination of the inhibition of the mobility of *Daphnia magna* Straus (Cladocera, Crustacea) –  
264 Acute toxicity test ISO (6341:2012), guidelines. *D. pulex* were used over the more common *Daphnia*  
265 *magna* as the former species are more commonly found in Irish water systems. The *D. pulex* was  
266 exposed to the intake and holding tank samples for 24 hours under static conditions at 20°C ± 2°C  
267 exposed to a photoperiod of 16 hr bright and 8 hr dark. Immobilisation, in percent, was calculated by  
268 comparing the samples to a negative control containing just the aerated spring water. *D. pulex* was

269 deemed immobile when no movement was observed after 15 seconds under gentle agitation.

270 Calculations were conducted as follows;

271

$$272 \quad \text{Percent immobilisation} = \left(1 - \frac{T}{C}\right) \times 100$$

273 Where T = Total number of mobile *D. pulex* in the treatment

274 C = Total number of mobile *D. pulex* in the control

275

## 276 2.5. Statistical analysis:

277 All statistical analyses were conducted using GRAPHPAD PRISM 8 and MINITAB 18. The data

278 generated were grouped and subject to normality tests (Anderson-Darling). T-tests and one-way

279 ANOVA with Tukey were used to identify significant differences in the variables.

280

## 281 3. Results

### 282 3.1. Physicochemical parameters:

283 The results determined for the physicochemical parameters investigated on the trial fish farm

284 intake and holding tank samples are displayed in Figure 2. Increases in concentrations from the

285 intake to the holding tank were observed in NO<sub>2</sub><sup>-</sup>, NO<sub>3</sub><sup>-</sup>, PO<sub>4</sub><sup>3-</sup>, BOD, COD and suspended solids.

286 Similar concentrations between the samples were observed in DO, temperature, pH, hardness and

287 alkalinity. The only parameter to display a decrease in concentration between the intake and holding

288 tank was NH<sub>4</sub><sup>+</sup>. When the intake and holding tank samples were compared via statistical analysis, a

289 significant difference was observed in the NO<sub>2</sub><sup>-</sup> (p = <0.001), NO<sub>3</sub><sup>-</sup> (p = 0.016), and COD levels (p =

290 0.011), where p < 0.05 indicated a statistically significant difference.

291

### 292 3.2. Ecotoxicological bioassays:

293 The *P. subcapitata* algal bioassay ISO (8692:2012), was performed on intake and holding tank

294 samples from the trial fish farm to determine whether the rate of growth was inhibited as a result of

295 exposure to either sample. The levels of growth rate inhibition observed in the intake and holding tank

296 samples can be found in Figure 3A. With the exception of the July sample, growth rate inhibition

297 decreased from the intake to the holding tank water. Statistical analysis was conducted between the

298 intake and holding tank samples and no significant differences were observed (p = 0.402).

299 The *D. pulex* crustacean bioassay ISO (6341:2012), was performed on intake and holding  
300 tank samples from the trial fish farm to determine whether immobilisation occurred as a result of  
301 exposure to either sample. The levels of immobility observed in the intake and holding tank water can  
302 be found in Figure 3B. Increased immobilisation was observed from the intake to the holding tank  
303 samples during May and July. Immobility remained unchanged in the month of June. August displayed  
304 a decrease. Statistical analysis was conducted between the intake and holding tank samples and no  
305 significant differences were observed ( $p = 0.390$ ).

306

#### 307 **4. Discussion**

308 In order to determine the potential effects aquaculture processes may have on Irish peatlands,  
309 intake and terminal holding tank water samples were compared to one another. Equally important was  
310 the potential effects the quality of the bog water may have on the fish themselves. Results from this  
311 study were therefore also compared to a range of studies previously conducted on a variety of fish  
312 farms that used different techniques (*e.g.* recirculating aquaculture systems, flow through systems,  
313 *etc.*), to culture a range of different species (*e.g.* shrimp, rainbow and brown trout, perch, catfish,  
314 salmon). In order to assess the quality of the water, recommended water quality parameters set out by  
315 the Statutory Instrument (S.I.), 77/2019 (European Communities Environmental Objectives – Surface  
316 Waters- Regulations 2019), and the Irish Environmental Protection Agency's (EPA), water quality  
317 parameters were used as a guidance (Environmental Protection Agency, 2001; Irish Stationery Office,  
318 2009). This was done so as, as far as the authors are aware, water quality parameters for aquaculture  
319 holding tank are currently unavailable in Ireland as the Irish EPA are actively investigating the  
320 regulation of freshwater aquaculture discharge (O'Neill *et al.*, 2019). Discharge licensing is currently  
321 assessed on an individual basis. It should be noted that the guidance values used (S.I. 77/2019,  
322 Freshwater Fish Directive [78/659/EEC], and/or the Irish Surface Water Regulations [1989]), are  
323 based on freshwater systems and not peatland environments. These freshwater parameters were  
324 included as the bogs freshwater receiving system is the Daingean /Philipstown River, 3.8 Km away  
325 from the farm. Emission levels set out in the fish farm's current discharge licence were not applicable  
326 here as composite sampling over 24 hours could not be conducted due to limitations. Also, the system  
327 is quite new and full operation only commenced in April.

328

329 4.1. Physicochemical analysis:

330 Nitrification is the process by which  $\text{NH}_4^+$  is firstly converted to  $\text{NO}_2^-$  and then to  $\text{NO}_3^-$  via  
331 enzymatic oxidation (Subba Rao *et al.*, 2017). The presence of  $\text{NH}_4^+$  in freshwater systems is an  
332 indication of recent pollution (Zhang *et al.*, 2011). The  $\text{NH}_4^+$  levels detected in the terminal holding tank  
333 water were lower than that of the intake water. Levels were also below the guidance value of 1 mg  
334  $\text{NH}_4^+$   $\text{L}^{-1}$ . This suggested that the fish farms and its treatment processes were reducing the levels of  
335  $\text{NH}_4^+$  present in the bog water.  $\text{NO}_2^-$  is also an indicator of recent pollution in freshwater systems  
336 (O'Neill *et al.*, 2019). Concentrations of  $\text{NO}_2^-$  detected in both sets of samples were above the Irish  
337 EPAs guidance values of 0.03 mg  $\text{L}^{-1}$ . The levels in the holding tank water were also significantly  
338 greater ( $p < 0.001$ ), than the intake. However, two very important points that needs to be highlighted  
339 when interpreting these results; 1) grab samples not composite samples were collected and analysed  
340 and, 2) water in the holding tank is only discharged from the farm when overflow occurs as a result of  
341 very heavy rainfall. Therefore, the concentration being released would be considerable reduced as the  
342 rain water would dilute the levels present. Results suggested that, although the treatment processes  
343 had successfully transformed  $\text{NH}_4^+$  to  $\text{NO}_2^-$ , it had not fully converted the nitrogenous waste to  $\text{NO}_3^-$ .  
344 However, the DO levels detected should have been high enough to avoid partial nitrification. The  $\text{NO}_2^-$   
345 levels may have been due to the water not being present in the algae and duckweed treatment bed for  
346 long enough. Also, as this is a new process, the algae and duckweed pond was not yet working to its  
347 maximum capacity (Table 1). Additional research would need to be conducted to establish the exact  
348 cause of the increase as the lack of ammonium could indicate that a low retention time may be  
349 unlikely.  $\text{NO}_3^-$  levels detected in the holding tank were also significantly greater ( $p = 0.016$ ), than that  
350 of the intake. However, all levels were well below the guidance value of 50 mg  $\text{L}^{-1}$ . The increases in  
351 the concentrations of these compounds were due to the rise in the feed applied as a result of  
352 increased stocking densities (Table 1). The release of these nitrogen compounds may assist in the  
353 restoration of the recovering bog as plants require nitrogen for growth and development (Xu *et al.*,  
354 2012). However, as peatlands are normally nutrient poor, additional research would need to be  
355 conducted.

356 High levels of phosphorus in freshwater systems can result in algal blooms and hypoxic  
357 conditions (O'Neill *et al.*, 2019). However, phosphorus is also an essential element for plant growth  
358 (Vance *et al.*, 2003).  $\text{PO}_4^{3-}$  levels detected in both samples were greater than the guidance value of

359 0.035 mg PO<sub>4</sub><sup>3-</sup> L<sup>-1</sup>. This rise was due to the increased application of feed (Table 1). Once again this  
360 concentration would be greatly decreased when diluted by rain water. Concentrations in the holding  
361 tank were greater than that of the intake however the difference was not statistically significant ( $p =$   
362 0.211), suggesting that the introduction of aquaculture processes did not appear to have altered the  
363 quality of the water. Additional research may need to be conducted in order to determine its effects on  
364 the receiving natural wetland, as well as to develop improved treatment methods if required. It should  
365 also be noted that the algae and duckweed channels used for treatment were not working to their  
366 maximum capacity (Table 1).

367         Similar DO levels were observed in both samples. Concentrations were above the guidance  
368 oxygen levels of 7 mg L<sup>-1</sup>. The use of the and inclusion of paddle wheels in the farm allows workers to  
369 maintain full control of oxygen levels within the farm ensuring optimum levels are sustained. Alam *et*  
370 *al.* (2007), da Silva *et al.* (2017), and O'Neill *et al.* (2019), have also suggested that concentrations of  
371  $\geq 4$  mg L<sup>-1</sup> are sufficient to maintain aquatic life, therefore current DO levels were not considered to be  
372 any cause for concern. Similar BOD levels were observed in both samples. With the exception of one  
373 spike observed in June, BOD levels were below the guidance values of 6 mg L<sup>-1</sup>. As the levels  
374 detected were below the guidance values, and the water quality remained unchanged, no issues were  
375 foreseen. COD levels detected in the holding tank were significantly greater ( $p = 0.011$ ), than that of  
376 the intake. Holding tank sample levels were also just above the guidance value of 40 mg L<sup>-1</sup>. This may  
377 have highlighted a potential issue. However, as previously mentioned, this level of COD would not be  
378 released as dilution would occur after the heavy levels of rainfall that would result in its release.

379         Suspended solids can cause increased gill irritation. Therefore, the guidance concentration of  
380 25 mg L<sup>-1</sup> set out by the Freshwater Fish Directive [78/659/EEC], was deemed a more suitable  
381 maximum allowable concentration (MAC), than the 50 mg L<sup>-1</sup> indicated in the Irish Surface Water  
382 Regulations [1989]. With the exception of one spike observed in May which may have resulted after  
383 recent rainfall, suspended solids were similar in both the samples, and levels remained below the  
384 guidance concentration.

385         Water temperatures remained consistent in both samples, as too did the pH values. Water  
386 may not be released from facilities if temperatures above 20°C are observed, and the temperature of  
387 the samples may have risen during its transportation to the laboratory. Therefore, there were no issues

388 with the temperature. The pH values were well within the recommended value of between pH 6 and  
389 pH 9.

390 Both alkalinity and hardness were measured as CaCO<sub>3</sub>. Results for hardness suggested that  
391 water was slightly too moderately hard. This correlates with water hardness maps of Ireland which  
392 indicated that water around Ballycon, Co Offaly was slight too moderately hard.

393 Some of the results observed (NO<sub>2</sub><sup>-</sup>, NO<sub>3</sub><sup>-</sup>, PO<sub>4</sub><sup>3-</sup> and COD), suggested potential issues. No  
394 research conducted on the use of peatlands for aquaculture could be found in the available literature.  
395 Additionally, this research only focused on one fish farm in a peatland setting. As a results all  
396 physicochemical results were then compared to a range of studies conducted on traditional fish farms  
397 (Table 3). All results obtained were similar to or below the concentrations determined in the previous  
398 aquaculture studies investigated, including NO<sub>2</sub><sup>-</sup>, NO<sub>3</sub><sup>-</sup>, PO<sub>4</sub><sup>3-</sup> and COD (Boaventura *et al.*, 1997;  
399 Camargo, 1994; Caramel *et al.*, 2014; Costanzo *et al.*, 2004; da Silva *et al.*, 2017; Guilpart *et al.*,  
400 2012; Lalonde *et al.*, 2014; Moreira *et al.*, 2010; Namin *et al.*, 2013; Noroozrajabi *et al.*, 2013; O'Neill  
401 *et al.*, 2019; Pulatsü *et al.*, 2004; Stephens and Farris, 2004a; Ziemann *et al.*, 1992; Živić *et al.*, 2009).  
402 This indicated that there appeared to be no observable differences between the water quality after  
403 traditional aquaculture settings, and that of bog-land settings.

404

#### 405 4.2. Ecotoxicological analysis:

406 Low levels of inhibition in the growth rate of the *P. subcapitata* were observed in both the  
407 intake and terminal holding tank water. This suggested that the quality of water in the intake samples  
408 and the holding tank water, in terms of its effect on the algae, remained unchanged and that the water  
409 within the bog was unlike to cause growth inhibition, therefore the recovery of the bog would not be  
410 affected. Most of the previous research using *P. subcapitata* in assessing water were based on  
411 polluted river systems and drainage water (Guéguen *et al.*, 2004; Ivanova and Groudeva, 2006).  
412 These studies displayed higher growth rate inhibition levels than those observed in this study. Only  
413 two previous studies could be found in the available literature that focused on the use of the algae in  
414 the context of aquaculture. The research conducted by O'Neill *et al.* (2019), found considerably higher  
415 inhibition levels than those reported in this study. Miashiro *et al.* (2012), and O'Neill *et al.* (2019), also  
416 reported stimulation of growth in the algae which could results in eutrophic conditions. As no  
417 stimulation of the algae was observed in this study, issues with eutrophic would seem highly unlikely.

418 Low levels of immobilisation in the *D. pulex* were observed in both samples. This suggested  
419 that the water quality seemed unlikely to cause any adverse effects on any of the aquatic organisms  
420 present in the bog. However, no studies in the available research focused on the use of *D. pulex* to  
421 assess aquaculture discharge, therefore additional research may need to be conducted.

422

## 423 **5. Conclusion**

424 No differences were observed between the physicochemical parameters of the intake and  
425 holding tank samples, with the exception of  $\text{NO}_2^-$ ,  $\text{NO}_3^-$  and COD, indicating that aquaculture  
426 processes did not adversely alter the quality of the water. The sub-lethal levels of toxicity observed in  
427 the ecotoxicological bioassays have also demonstrated that the introduction of aquaculture processes  
428 into peatlands may be unlikely to cause any adverse effects on the ecosystem and organisms within it.  
429 This suggested that the use of cutaway bog as future locations for integrated multitrophic aquaculture  
430 (IMTA) processes holds promising potential. The use of bogs may aid in achieving the aims set on in  
431 the Food Wise 2025 initiative to increase Irish aquaculture production to 81,700 by 2023, assisting in  
432 the enhancing freshwater aquaculture processes. This constitutes the first study to report on  
433 sustainable development of new fish farms in cutaway bogs that were powered by wind turbine and  
434 used algae and duckweed as natural processes for treating water adopting organic principles. IMTA  
435 may also assist in providing an economically sound alternative for sustainable land use for  
436 stakeholders once all peat harvesting processes cease. However, while results so far have indicated  
437 positivity, additional research needs to be conducted in order to fully appreciate all parameters  
438 governing large scale up of this peatland aquaculture process to ensure commercial viability that  
439 includes fine tuning hydronamics, microbial ecology and probiotic benefits of algal, bacterial and  
440 duckweed interactions.

441

## 442 **Conflicts of Interest**

443 The authors declare that there are no competing interests or conflicts of interest with respect  
444 to the publication of this article.

445

## 446 **Acknowledgements**

447 The authors would like to thank Athlone Institute of Technology (President Seed Fund), Bord  
448 lascaigh Mhara (co-funded by the Irish Government and European Union), also under the EcoAqua  
449 and CENAKVA projects for providing financial support for this research. The authors also  
450 acknowledge Bord lascaigh Mhara for furnishing aerial image of AquaMona farm used in graphic  
451 abstract, and to Bord na Móna for providing access to same farm in order to conduct this research.

638 **Highlights**

639

- 640 • Peatlands (bog) offer a new sustainable approach for integrated multitrophic aquaculture
- 641 using organic principles
- 642 • Trial farm within cutaway bog showed favourable intake and holding tank water quality
- 643 • Use of algae and duckweed show promise as natural means of treating rearing water
- 644 • Ecotoxicological analysis revealed no differences between intake and holding tank water.
- 645 • Water quality findings were similar to previously reported traditional aquaculture processes.
